ABSTRACT

High school timetabling problems consist in building periodic timetables for class-teacher meetings considering compulsory and non-compulsory requirements. This family of problems has been widely studied since the 1950s, mostly via mixed-integer programming and metaheuristic techniques. However, the efficient search of optimal or near-optimal solutions is still a challenge for many problems of practical size. In this paper, we investigate mixed-integer programming formulations and a parallel metaheuristic based algorithm for solving high school timetabling problems with compactness and balancing requirements. We propose two pattern-based formulations and a solution algorithm that simultaneously exploits column generation and a team of metaheuristics to build and improve solutions. Extensive computational experiments conducted with real-world instances demonstrate that our formulations are competitive with the best existing high school timetabling formulations, while our parallel algorithm presents superior performance to alternative methods available in the literature.

1. Introduction

Educational timetabling problems consist in assigning meetings between teachers (or exams) and students, considering a list of different hard (mandatory) or soft (non-mandatory) requirements. A timetable that satisfies all hard requirements is said to be feasible, and a timetable that is feasible and also has a minimum number of violated soft requirements is said to be optimal.

The automated design of educational timetables started in the late 1950s, with methods that tried to encode manual procedures. Junginger (1986) presents a review of the first papers on timetabling problems, showing that simple heuristics were the most common solution methods. The article also reports on early computer programs that had been developed using exact methods (Gotlieb, 1963). However, as expected, they were able to address only small instances of simplified problems. Since then, the timetabling literature has been widely extended. Current research can be categorized around three main educational timetabling

variants: university course timetabling (Lewis, 2008), examination timetabling (Qu, Burke, McCollum, Merlot, & Lee, 2009) and high school timetabling (De Werra, 1985; Pillay, 2014).

In this paper, we address the high school timetabling problem (HSTP). In its most basic version, which is NP-complete (Even, Itai, & Shamir, 1975), the HSTP requires that schedules contain no clashes and that no teacher is assigned outside of his working hours. Here, we consider an HSTP variant with additional requirements such as: enforcing double lessons for some classes' subjects (two consecutive lessons between a teacher and a class within the same day), avoiding idle periods (a free period between busy periods within the same day in teachers' schedules), and prioritizing teachers' schedules containing a minimum number of working days. These latter requirements are common in situations where a teacher works on multiple schools. An ideal schedule is the one in which a teacher works the minimum number of days to meet his/her teaching requirements. Any additional working day above this minimum amount is called *extra working days* and should be balanced among the teachers.

Traditional compact mixed-integer programming (MIP) models (Dorneles, de Araújo, & Buriol, 2014; Kristiansen, Sørensen, & Stidsen, 2015; Sørensen & Dahms, 2014) for high school timetabling problems are known to have weak linear programming relaxations.

Stronger MIP formulations have been proposed (Dorneles, de Araújo, & Buriol, 2017; Fonseca, Santos, Carrano, & Stidsen, 2017). However, these formulations are still ineffective when implemented to solve medium and large size instances using current black-box solvers. Given these limitations, many researchers have focused on combining heuristic algorithms and relaxation methods to obtain high-performance hybrid approaches with some information on the quality of the schedules. On the one hand, research on heuristic algorithms aims to compute high-quality solutions with reduced computational effort. On the other hand, the research on relaxation methods aims to compute tight lower bounds on the optimal solutions.

The quality of the lower bounds obtained by compact formulations can sometimes be improved by solving the linear relaxation of extended MIP formulations via column generation. Indeed, some extended formulations proposed to HSTPs have shown strong lower bounds (Dorneles et al., 2017; Papoutsis, Valouxis, & Housos, 2003; Santos, Uchoa, Ochi, & Maculan, 2012). Simultaneously, recent heuristic approaches (Saviniec & Constantino, 2017; Saviniec, Santos, & Costa, 2018; Skoullis, Tassopoulos, & Beligiannis, 2017) have been shown to provide good quality solutions. Nevertheless, even with these recent advances, optimality gaps for medium and large size available instances are still not closed and motivate further research in both the development of good lower and upper bounds.

In this paper, we propose two new MIP formulations for the addressed HSTP variant. The first formulation has a relatively small number of variables when applied to realistic instances. This formulation is strengthened using Fenchel cuts (Boyd, 1994a; 1994b) and solved with a black-box solver. The second formulation has an enormous number of variables, even for small-size problems, and we therefore, resort to column generation to solve its linear relaxation.

We also propose a cooperative parallel solution algorithm. The method uses a team of metaheuristics to construct and improve solutions. The solution algorithm also incorporates new agents based on the previously mentioned column generation. These agents use partial/fractional solutions obtained by the column generation to (i) obtain lower bounds for the problem and (ii) extend them to complete solutions using an original method that relies on a fix-and-optimize heuristic (Pochet & Wolsey, 2006) with an inbuilt repair procedure based on proximity search (Fischetti & Monaci, 2014).

To assess the proposed approaches, we conduct a thorough computational study with instances of the HSTP variant of interest. The methods are also adapted and tested on two related versions of the problem. The remainder of this paper is organized as follows. Section 2 presents a literature review on techniques for high school timetabling. Section 3 formally defines the problem under study. Section 4 is dedicated to the presentation of the proposed MIP models, while Section 5 details our solution algorithm. Section 6 provides the computational experiments and analysis, and Section 7 presents final remarks and suggestions for future research. Two appendices complete this article: Appendix A presents an additional MIP model (Saviniec et al., 2018) while Appendix B provides details on stand-alone metaheuristic methods for the problem. Both the additional model and stand-alone heuristics are employed by the proposed parallel algorithm.

2. Techniques for HSTP

Since the first studies in the late 1950s, the scientific literature has reported numerous papers dealing with solution techniques for high school timetabling problems. In this section, we review the most successful of these approaches.

Up to the 2000s, the high school timetabling research had been mostly based on independent case studies, making it difficult to compare different solution methods. The first high school timetabling dataset to be widely available appeared in the early 2000s. Souza (2000) introduced a small set of instances from Brazilian high schools,¹ which became a commonly used benchmark, being addressed later by both heuristics (Dorneles et al., 2014; Santos, Ochi, & Souza, 2005; Saviniec & Constantino, 2017; Saviniec et al., 2018; Souza, Maculan, & Ochi, 2004) and mixed-integer programming techniques (Dorneles et al., 2014; 2017; Santos et al., 2012). This dataset was extended with new real cases² proposed by Saviniec and Constantino (2017). The leading heuristic methods for solving this new problem are parallel metaheuristic-based algorithms (Saviniec et al., 2018).

A second high school timetabling dataset appeared in the late 2000s. Beligiannis, Moschopoulos, Kaperonis, and Likothanassis (2008) introduced a set of real-case instances from Greek high schools³ that also became the subject of several studies (Beligiannis, Moschopoulos, & Likothanassis, 2009; Skoullis et al., 2017; Tassopoulos & Beligiannis, 2012; Zhang, Liu, M'Hallah, & Leung, 2010). The leading heuristic method reported for this dataset is a Cat Swarm Optimization based algorithm (Skoullis et al., 2017).

During the 7th International Conference on the Practice and Theory of Automated Timetabling (PATAT, 2008), the timetabling community proposed an XML-based format to represent different high school timetabling problems and create a unified set of benchmark instances (Post et al., 2012). This format, called XHSTT (Post et al., 2014), established rules to model the most common high school timetabling requirements found around the world. The XHSTT format allows the description of *generalized high school timetabling problems* (GHSTP). After its creation, new instances from different countries have been added to the XHSTT repository,⁴ including some of those proposed by Souza (2000). Such instances were used in the Third International Timetabling Competition (ITC-2011) devoted to HSTPs. The method with better performance for these instances is the heuristic solver GOAL (Fonseca, Santos, Toffolo, Brito, & Souza, 2016), which won the ITC-2011. An updated version of GOAL is described in Fonseca, Santos, and Carrano (2016).

Regarding the use of mixed-integer programming techniques, different compact formulations have been proposed to HSTPs (Al-Yakoob & Sherali, 2015; Dorneles et al., 2014; Kristiansen et al., 2015; Sørensen & Dahms, 2014; Santos et al., 2012). However, all of these formulations have shown weak linear relaxations. The strongest formulation for high school timetabling is based on a multi-commodity flow problem, first proposed for problems of Brazilian high schools (Dorneles et al., 2017) and later adapted to solve GHSTP (Fonseca et al., 2017). Extended formulations solved by column generation have also been proposed. Santos et al. (2012) and Dorneles et al. (2017) proposed different formulations for the Brazilian case, which showed similar results regarding the quality of their lower bounds. Finally, a column generation lower bounding procedure was also proposed in Al-Yakoob and Sherali (2015), for instances based on Kuwaiti high schools timetabling problems.

As mentioned before, the literature has reported many other case studies dealing with solution techniques for high school timetabling problems. For a more detailed review of these methods, we refer the interested reader to Pillay (2014).

3. Problem definition

We consider the high school timetabling problem studied in Saviniec et al. (2018), which originated in the context of Brazilian public high schools. The problem structure is represented in Fig. 1. The school has a set of classes C and a set of teachers T . Classes are disjoint groups of students enrolled in the same list of subjects. Classes should have no free periods during the week. Each class' subject has a number of weekly lessons that are taught by a preassigned teacher. The set of all classes' subjects is called "Courses" (R) and each class' subject is called "a course". Teachers may be unavailable in some periods/days. Given these input data, the goal is to obtain a weekly timetable specifying the schedule for all courses in a particular shift (morning, afternoon, or evening). A timetable is constructed for each independent shift, and it usually spreads over the set of weekdays D (Monday to Friday) with (usually) five periods each. We define H as the set of periods per day and refer to periods as a set of timeslots $(d, h) \in D \times H$.

The timetabling process must fulfill the following hard requirements:

1. *Meeting of weekly lessons*: the lessons of each course $r \in R$ must be assigned.
2. *No clashes in classes' schedules*: each class $c \in C$ must attend exactly one lesson per period.
3. *No clashes in teachers' schedules*: each teacher $t \in T$ must teach at most one lesson per period.
4. *No assignment of teachers in their unavailable periods*: teachers must not be assigned to periods in which they are unavailable.

The following soft requirements are also considered:

5. *No daily workload violation for courses*: for each course $r \in R$, there is a soft limit $\tilde{\delta}_r$ on the amount of lessons per day to each given class.
6. *No gaps in courses' schedules*: gaps in courses' schedules should be avoided. A *gap* is a period splitting the daily meetings of a course to a given class into non-consecutive lessons.
7. *Meeting of double lessons for courses*: for each course $r \in R$, there is a specified minimum number of consecutive double lessons $\tilde{\pi}_r$ that should be met.
8. *No idle periods in teachers' schedules*: teachers should not have free periods between busy periods within the same day. For the purpose of this requirement, unavailable periods are considered as busy periods. Therefore, they are not computed as idle periods.
9. *Minimizing the number of working days for teachers*: teachers should be scheduled to come to school the minimum possible number of days.
10. *Balancing on teachers' extra working days*: the extra working days should be balanced among teachers. The number of extra working days for a teacher $t \in T$ is the difference between the number of worked days and an estimated lower bound \hat{d}_t , defined later in Table 1.

4. Mixed integer programming models

This section presents our two models for the problem. Both models are extensive formulations as they rely on teachers/classes

Table 1

Input parameters of a high school timetabling instance.

Notation	Definition
Sets	
C	The set of classes.
T	The set of teachers.
D	The set of weekdays.
H	The set of periods per day.
$H_{td} \subseteq H$	The subset of periods in day $d \in D$ for which teacher $t \in T$ is available.
R	The set of courses, as defined in Section 3.
$R_c \subseteq R$	The subset of courses associated to a class $c \in C$.
$R_t \subseteq R$	The subset of courses associated to a teacher $t \in T$.
Parameters	
$\tilde{\theta}_r \in \mathbb{N}$	The number of weekly lessons for a course $r \in R$.
$\tilde{\delta}_r \in \mathbb{N}$	The daily limit for the number of lessons of a course $r \in R$.
$\tilde{\pi}_r \in \mathbb{N}$	the desired minimum number of double lessons for a course $r \in R$.
$\tilde{d}_t = \left\lceil \frac{\sum_{r \in R_t} \tilde{\theta}_r}{ H } \right\rceil$	A lower bound on the minimum number of days for which a teacher $t \in T$ can be assigned and still meet his/her teaching requirements.

Table 2

Additional notation and decision variables used in formulation EF1.

Notation	Definition
Sets	
L	The set of assignment layouts that a course r (or teacher t) can follow in a day.
Parameters	
$\tilde{\mu}_{lh} \in \{0, 1\}$	Indicates whether a layout $l \in L$ has an assignment at period $h \in H$.
$\tilde{a}_l \in \mathbb{N}$	The number of assignments in a layout l .
$\tilde{e}_{rl} \in \mathbb{N}$	The number of lessons that exceed the daily limit $\tilde{\delta}_r$ in a layout l for a course r .
$\tilde{h}_l \in \mathbb{N}$	The number of gaps in a layout l for courses.
$\tilde{\omega}_l \in \mathbb{N}$	The number of consecutive double lessons in a layout l for courses.
$\tilde{\phi}_l \in \{0, 1\}$	Indicates whether the number of assignments in a layout l is greater than zero.
$\tilde{i}_{tdl} \in \mathbb{N}$	The number of idle periods in a layout l for a teacher t in a day d .
Decision variables	
$x_{rdl} \in \{0, 1\}$	Indicates whether a course r follows a layout l in a day d .
$y_{tdl} \in \{0, 1\}$	Indicates whether a teacher t follows a layout l in a day d .
Auxiliary variables	
$\tilde{\pi}_r \in \mathbb{N}$	The number of unmet weekly double lessons for a course r .
$\tilde{\beta} \in \mathbb{N}$	The largest value among all teachers' extra working days.

meeting patterns. Extensive formulations have been used for timetabling problems, for example, in Papoutsis et al. (2003), Santos et al. (2012), and Dorneles et al. (2017). Different from the strategy used in these papers, we propose a type of pattern with limited information: teachers patterns only indicate if a teacher is teaching or not in a given period (and relegate the decision on which class they are teaching to the master problem) while courses patterns only indicate if a given course is being taught or not in a given period (and relegate the decision on the class to which this course is being taught to the master problem).

We call the limited-information patterns 'layouts'. Our first extensive formulation, EF1, exploits the fact that the cardinality of the sets of layouts is much smaller than the cardinality of traditional (full-information) patterns. The second formulation, EF2, considers a more traditional approach with weekly layouts indicating the full schedule of a teacher. Both models and solution strategies are discussed in the remainder of this section, using the notation in Table 1.

4.1. Extended formulation 1

The first model (EF1) uses the idea of assignment layouts for the daily schedules of teachers and courses. A *daily assignment layout* is defined as a binary vector of size $|H|$ in which the h th position is associated with the h th period of the day. For a teacher, a bit value of "1" indicates that the teacher is assigned at that period, while for a course it indicates that there is one lesson associated with that course at that period.

The number of all possible daily layouts for a course or teacher (disregarding unavailable periods) is given by $2^{|H|}$. For $|H| = 5$, a teaching layout '00000' for a given day indicates that the associated teacher has that day off while a layout '00111' indicates that the teacher has lessons assigned to him/her in the last three teaching periods of the day. This definition of "layouts" is different from the one used in most of the literature which usually explicitly codify which class the teacher should meet at each timeslot. Here, for teacher layouts, there is only the definition of the presence or absence of the considered teacher in a timeslot. Analogously, for course layouts, a layout '11000' indicates that a double lesson of that subject is taking place in the first two periods of the day while a layout '10100' represents an undesired gap between two lessons of the same course.

Table 2 presents the data of the HSTP in an appropriate format and also lists the two sets of binary decision variables, x_{rdl} and y_{tdl} . These binary variables indicate whether a course $r \in R$ (x_{rdl}) or teacher $t \in T$ (y_{tdl}) follows an assignment layout $l \in \{0, 1, \dots, 2^{|H|} - 1\}$ on day $d \in D$. Model EF1 can thus be written as:

$$\begin{aligned} \text{Minimize} \quad & \sum_{r \in R} \sum_{d \in D} \sum_{l \in L} (\alpha_5 \tilde{e}_{rl} + \alpha_6 \tilde{h}_l) x_{rdl} + \alpha_7 \sum_{r \in R} \tilde{\pi}_r \\ & + \sum_{t \in T} \sum_{d \in D} \sum_{l \in L} (\alpha_8 \tilde{i}_{tdl} + \alpha_9 \tilde{\phi}_l) y_{tdl} + \alpha_{10} \tilde{\beta} \end{aligned} \quad (1)$$

Subject to:

$$\sum_{d \in D} \sum_{l \in L} \tilde{a}_l x_{rdl} = \tilde{\theta}_r \quad \forall r \in R \quad (2)$$

Table 3

Notation used to define Fenchel cuts to formulation EF1.

Notation	Definition
Sets	
$K_{td} = \{1, \dots, H_{td} \}$	The set of all possible number of lessons for a teacher t in a day d .
$Q_{rd} = \{1, \dots, \min(H_{td} , \tilde{\theta}_r)\}$	The set of all possible number of lessons for a course r in a day d . In this definition, t is the teacher associated with course r .
$A_k \subseteq L$	The subset of layouts $l \in L$ which have exactly k bits at value 1, for $k \in \{1, \dots, H \}$.
Additional variables	
$w_{tdk} \in \{0, 1\}$	Indicates whether a teacher t has exactly k lessons in a day d .
$v_{rdk} \in \{0, 1\}$	Indicates whether a course r has exactly k lessons in a day d .

$$\sum_{r \in R_t} \sum_{l \in L} \tilde{\mu}_{lh} x_{rdl} = 1 \quad \forall c \in C; d \in D; h \in H \quad (3)$$

$$\sum_{l \in L} x_{rdl} = 1 \quad \forall r \in R; d \in D \quad (4)$$

$$\sum_{l \in L} y_{tdl} = 1 \quad \forall t \in T; d \in D \quad (5)$$

$$\hat{\pi}_r \geq \tilde{\pi}_r - \sum_{d \in D} \sum_{l \in L} \tilde{\omega}_l x_{rdl} \quad \forall r \in R \quad (6)$$

$$\hat{\beta} \geq \sum_{d \in D} \sum_{l \in L} \tilde{\phi}_l y_{tdl} - \tilde{d}_t \quad \forall t \in T \quad (7)$$

$$\sum_{l \in L} \tilde{\mu}_{lh} y_{tdl} = \sum_{r \in R_t} \sum_{l \in L} \tilde{\mu}_{lh} x_{rdl} \quad \forall t \in T; d \in D; h \in H \quad (8)$$

$$\hat{\pi}_r \geq 0 \quad \forall r \in R \quad (9)$$

$$\hat{\beta} \geq 0 \quad (10)$$

$$x_{rdl} \in \{0, 1\} \quad \forall r \in R; d \in D; l \in L \quad (11)$$

$$y_{tdl} \in \{0, 1\} \quad \forall t \in T; d \in D; l \in L \quad (12)$$

Objective function (1) minimizes violations of soft requirements 5 to 10, in which α_i is a penalty parameter associated with the relative importance of the i th requirement. Note that for requirement 10, we use a min-max approach where the objective is to minimize the 'extra busy days' of the teacher with maximum value of this parameter. This choice is in accord with what is done in previous papers but has the issue of being *blind* to the load of teachers other than the most loaded one (in terms of busy days). Alternative modeling could penalize the total sum (over all teachers) of extra days, either linearly or quadratically. In the experiments we used the objective function as shown in (1) and (7). Constraints (2) ensure that the weekly lessons of all courses are scheduled. Constraints (3) avoid clashes in classes' schedules. Constraints (4) and (5) ensure that a single layout is assigned to each course and each teacher on a given day, respectively. Constraints (6) and (7) link the auxiliary variables to the decision variables in order to quantify violations of soft requirements 7 and 10: constraints (6) compute the number of unmet double lessons for each course while constraints (7) capture the largest value among all teachers' extra working days. Finally, the linking constraints (8) ensure that the daily schedules of teachers match their courses' schedules.

To avoid assigning teachers to their unavailable periods, we preprocess the associated variables and forbid layouts which contain

infeasible assignments. This task can be accomplished by setting the following variables to zero:

$$y_{tdl} = 0 \quad \forall t \in T; d \in D; l \in L; h \in H \setminus H_{td}; \tilde{\mu}_{lh} > 0 \quad (13)$$

$$x_{rdl} = 0 \quad \forall t \in T; r \in R_t; d \in D; l \in L; h \in H \setminus H_{td}; \tilde{\mu}_{lh} > 0 \quad (14)$$

Program (1)–(12) is also augmented with the additional valid cuts (15), which specify that a teacher cannot work less than the minimum necessary number of days \tilde{d}_t (Souza, 2000).

$$\sum_{d \in D} \sum_{l \in L} \tilde{\phi}_l y_{tdl} \geq \tilde{d}_t \quad \forall t \in T \quad (15)$$

We note that $|H|$ is a small constant for some high school timetabling problems of practical size (e.g., for the case of Brazilian institutions it is common to have $|H| = 5$). This fact, associated with the new layout patterns with reduced cardinality, keeps the number of variables of EF1 reasonably low. This allows for black-box MIP solvers to be used for obtaining solutions. In order to further increase the efficiency of the methods, we strengthen EF1 with valid inequalities, as described in the following.

4.1.1. Cutting planes generation for EF1

In this section, we describe cuts that can be added to the root node of program (1)–(12) to strengthen its linear relaxation. The cuts are generated by using Fenchel enumeration cutting planes technique (Boyd, 1994a; 1994b). The idea is adapted from Santos et al. (2012), which employed these cuts to a different formulation of the HSTP problem. In Santos et al. (2012), the cuts are used to strengthen a column generation procedure instead of an explicitly generated model.

Let us consider the notation defined in Table 3. We augment formulation EF1 by introducing auxiliary binary variables w_{tdk} and v_{rdk} . These new variables are linked to the original ones by means of constraints:

$$\sum_{l \in A_k} y_{tdl} = w_{tdk} \quad \forall t \in T; d \in D; k \in K_{td} \quad (16)$$

$$\sum_{l \in A_k} x_{rdl} = v_{rdk} \quad \forall r \in R; d \in D; k \in Q_{rd} \quad (17)$$

Now consider each of the following valid polyhedra:

- Polyhedron Π_t (for lessons of a teacher t):

$$\sum_{d \in D} \sum_{k \in K_{td}} k w_{tdk} = \sum_{r \in R_t} \tilde{\theta}_r \quad (18)$$

$$\sum_{k \in K_{td}} w_{tdk} \leq 1 \quad \forall d \in D \quad (19)$$

$$w_{tdk} \in \{0, 1\} \quad \forall d \in D; k \in K_{td} \quad (20)$$

Table 4

Notation and decision variables used in formulation EF2.

Notation	Definition
Sets	
S_t	The set of all possible weekly schedules that a teacher $t \in T$ can follow.
$T_c \subseteq T$	The set of teachers that teach to class $c \in C$.
Parameters	
f_{ti}	The cost associated with violations of requirements 5 to 9 in the i th weekly schedule of a teacher t .
$\rho_{ti}^{cdh} \in \{0, 1\}$	Indicates whether a teacher t teaches class c in a schedule $i \in S_t$ at period h of a day d .
$\phi_{ti} \in \mathbb{N}$	The number of working days for a teacher t in a schedule $i \in S_t$.
Decision variables	
$\lambda_{ti} \in \{0, 1\}$	Indicates whether a teacher t follows a weekly schedule $i \in S_t$.
Auxiliary variables	
$\hat{\beta} \in \mathbb{N}$	The largest value among all teachers' extra working days.

Constraints (18) ensure that the weekly workload of teacher t is met, and constraints (19) impose that at most one variable w is active for each day.

- Polyhedron Π_r (for lessons of a course r):

$$\sum_{d \in D} \sum_{k \in Q_{rd}} kv_{rdk} = \tilde{\theta}_r \quad (21)$$

$$\sum_{k \in Q_{rd}} v_{rdk} \leq 1 \quad \forall d \in D \quad (22)$$

$$v_{rdk} \in \{0, 1\} \quad \forall d \in D; k \in Q_{rd} \quad (23)$$

Constraints (21) ensure that the correct weekly workload of course r is met, and constraints (22) impose that at most one variable v is active for each day.

Let \bar{w} be the fractional values of variables w in the optimal solution of the linear program of augmented formulation EF1. By enumerating all integer feasible solutions $\hat{w} \in \Pi_r$, we can easily check if there is an hyperplane separating \bar{w} from the convex hull defined by the feasible integer points $\hat{w} \in \Pi_r$. This is done by solving the following oracle linear program \mathcal{O}_t :

$$\text{Maximize } z_t = \sum_{d \in D} \sum_{k \in K_{td}} \bar{w}_{tdk} a_{tdk} \quad (24)$$

Subject to:

$$\sum_{d \in D} \sum_{k \in K_{td}} \hat{w}_{tdk} a_{tdk} \leq 1 \quad \forall \hat{w} \in \Pi_t \quad (25)$$

$$a_{tdk} \geq 0 \quad \forall d \in D; k \in K_{td} \quad (26)$$

Let (z_t^*, a_{tdk}^*) be the optimal solution of \mathcal{O}_t . If $z_t^* > 1$, then point \bar{w} lies outside of Π_r and

$$\sum_{d \in D} \sum_{k \in K_{td}} a_{tdk}^* w_{tdk} \leq 1 \quad (27)$$

is a valid inequality that is violated by the current fractional solution. The exact same idea can be used to obtain violated valid inequalities associated with variables v_{rdk} .

The described inequalities are iteratively identified and inserted into program (1)–(12) at the root node. At each iteration, we solve the linear program of EF1 and call the oracle problems for each teacher and each course. Any violated inequality is inserted in the program. If no new violated inequality is found and the solution is still fractional, then we proceed to branch.

4.2. Extended formulation 2

This section presents the second extended formulation, denoted by EF2. The variables of EF2 represent complete weekly schedules of teachers. A *weekly schedule* for a teacher \tilde{t} is any assignment of binary values to variables $y_{\tilde{t}dl}$ and $x_{\tilde{t}rdl}$ (for all $r \in R_{\tilde{t}}$) in model EF1, that satisfies constraints (2), (4)–(6), (8) and (13)–(15). Note that contrary to EF1, EF2 has columns containing full schedule information. We define S_t as the set of all feasible weekly schedules for a teacher $t \in T$. A timetable can thus be represented by a set of binary variables λ_{ti} , which indicate whether each teacher $t \in T$ follows a weekly schedule $i \in S_t$.

Considering the additional notation defined in Table 4, the mixed-integer program of EF2 can be written as:

$$\text{Minimize } \sum_{t \in T} \sum_{i \in S_t} f_{ti} \lambda_{ti} + \alpha_{10} \hat{\beta} \quad (28)$$

Subject to:

$$(\xi_t^1) \quad \sum_{i \in S_t} \lambda_{ti} = 1 \quad \forall t \in T \quad (29)$$

$$(\xi_{cdh}^2) \quad \sum_{t \in T_c} \sum_{i \in S_t} \rho_{ti}^{cdh} \lambda_{ti} = 1 \quad \forall c \in C; d \in D; h \in H \quad (30)$$

$$(\xi_t^3) \quad \hat{\beta} - \sum_{i \in S_t} \phi_{ti} \lambda_{ti} \geq -\tilde{d}_t \quad \forall t \in T \quad (31)$$

$$\hat{\beta} \geq 0 \quad (32)$$

$$\lambda_{ti} \in \{0, 1\} \quad \forall t \in T; i \in S_t \quad (33)$$

Objective function (28) minimizes the cost of violating requirements 5 to 9 in selected weekly teacher schedules, plus the cost associated with soft requirement 10. Constraints (29) ensure that a single weekly schedule is selected for each teacher. Constraints (30) avoid clashes in classes' schedules, and constraints (31) capture the maximum number of extra working days among all teachers. In this formulation, we also indicate the dual variables associated with constraints (29)–(31) when the integrality constraints (33) are relaxed.

For instances of practical size, formulation EF2 has a huge number of variables which usually forbids the explicit generation of the model within a black-box solver. Even if the explicit writing of the problem is possible, it usually results in models that cannot be tackled by current solvers. However, as optimal solutions are defined by small subsets of these variables, we can use column

Table 5Notation used in the formulation of a subproblem Q_t .

Notation	Definition
Sets	
L	The set of all possible assignment layouts that a teacher t or a course $r \in R_t$ can follow in a day.
$C_t \subseteq C$	The set of classes taught by teacher t .
$R_{ct} \subseteq R$	The set of courses belonging to class c which are taught by teacher t .
Parameters	
$\tilde{\mu}_{lh} \in \{0, 1\}$	Indicates whether a layout $l \in L$ has an assignment at period $h \in H$.
$\tilde{a}_l \in \mathbb{N}$	The number of assignments in a layout l .
$\tilde{e}_{rl} \in \mathbb{N}$	The number of lessons that exceed the daily limit \tilde{d}_r in a layout l for a course $r \in R_t$.
$\tilde{h}_l \in \mathbb{N}$	The number of gaps in a layout l for courses.
$\tilde{\omega}_l \in \mathbb{N}$	The number of consecutive double lessons in a layout l for courses.
$\tilde{\phi}_l \in \{0, 1\}$	Indicates whether the number of assignments in a layout l is greater than zero.
$\tilde{i}_{tdl} \in \mathbb{N}$	The number of idle periods in a layout l for a teacher t in a day d .
Decision variables	
$y_{dl} \in \{0, 1\}$	Indicates whether teacher t follows a layout $l \in L$ in a day d .
$x_{rdl} \in \{0, 1\}$	Indicates whether a course $r \in R_t$ follows a layout $l \in L$ in a day d .
Auxiliary variables	
$\hat{\pi}_r \in \mathbb{N}$	The number of unmet weekly double lessons for a course r .

generation (Desaulniers, Desrosiers, & Solomon, 2005) as an effective tool to solve the associated relaxed problem. The procedure is described in the following.

4.2.1. Column generation approach for EF2

The proposed column generation procedure defines the master problem as the linear relaxation of program (28)–(33). The initial master program contains a reduced number of artificial columns, to which we assign high costs. New columns are generated via $|T|$ pricing subproblems Q_t , which select the most attractive weekly schedules (columns) for teachers. At each iteration, each subproblem Q_t is solved to obtain the column that has the smallest reduced cost, for teacher t , based on the dual values of the associated master program solution. The new columns are inserted into the master program, which is solved again, and the process continues until there is no column with a reduced negative cost.

With the notation defined in Table 5, a mixed-integer program for the pricing subproblems Q_t can be written as:

$$\begin{aligned}
 \text{Minimize } \bar{c}_t = & \sum_{r \in R_t} \sum_{d \in D} \sum_{l \in L} (\alpha_5 \tilde{e}_{rl} + \alpha_6 \tilde{h}_l) x_{rdl} + \alpha_7 \sum_{r \in R_t} \hat{\pi}_r \\
 & + \sum_{d \in D} \sum_{l \in L} (\alpha_8 \tilde{i}_{tdl} + \alpha_9 \tilde{\phi}_l) y_{dl} \\
 & - \xi_t^1 - \sum_{c \in C_t} \sum_{d \in D} \sum_{h \in H} \xi_{cdh}^2 \sum_{r \in R_{ct}} \sum_{l \in L} \tilde{\mu}_{lh} x_{rdl} \\
 & + \xi_t^3 \sum_{d \in D} \sum_{l \in L} \tilde{\phi}_l y_{dl}
 \end{aligned} \quad (34)$$

Subject to:

$$\sum_{d \in D} \sum_{l \in L} \tilde{a}_l x_{rdl} = \tilde{\theta}_r \quad \forall r \in R_t \quad (35)$$

$$\sum_{r \in R_{ct}} \sum_{l \in L} \tilde{\mu}_{lh} x_{rdl} = 1 \quad \forall c \in C_t; d \in D; h \in H \quad (36)$$

$$\sum_{l \in L} x_{rdl} = 1 \quad \forall r \in R_t; d \in D \quad (37)$$

$$\sum_{l \in L} y_{dl} = 1 \quad \forall d \in D \quad (38)$$

$$\sum_{r \in R_t} \sum_{l \in L} \tilde{\mu}_{lh} x_{rdl} = \sum_{l \in L} \tilde{\mu}_{lh} y_{dl} \quad \forall d \in D; h \in H \quad (39)$$

$$\hat{\pi}_r \geq \tilde{\pi}_r - \sum_{d \in D} \sum_{l \in L} \tilde{\omega}_l x_{rdl} \quad \forall r \in R_t \quad (40)$$

$$\sum_{d \in D} \sum_{l \in L} \tilde{\phi}_l y_{dl} \geq \tilde{d}_t \quad (41)$$

$$\hat{\pi}_r \geq 0 \quad \forall r \in R_t \quad (42)$$

$$x_{rdl} \in \{0, 1\} \quad \forall r \in R_t; d \in D; l \in L \quad (43)$$

$$y_{dl} \in \{0, 1\} \quad \forall d \in D; l \in L \quad (44)$$

Objective function (34) is the reduced cost \bar{c}_t based on the dual values ξ_t^1 , ξ_{cdh}^2 and ξ_t^3 associated with constraints (29)–(31) of the master problem. Constraints (35) ensure that the weekly lessons of all courses belonging to teacher t are scheduled. Constraints (36) forbid clashes in classes' schedules. These constraints are necessary since the same teacher can be associated with different courses (e.g., a teacher who teaches mathematics and physics to the same class). Constraints (37) and (38) ensure that a teacher t and their courses $r \in R_t$ follow only one layout per day. The linking constraints (39) ensure that the daily schedules of a teacher t match his/her courses' schedules. Constraints (40) compute the number of unmet double lessons for courses. Finally, constraints (41) are valid inequalities stating that a teacher t does not work less than the minimum necessary number of days \tilde{d}_t .

As before, to avoid violating teachers' unavailable periods, we preprocess the variables as follows.

$$y_{dl} = 0 \quad \forall d \in D; l \in L; h \in H \setminus H_{td}; \tilde{\mu}_{lh} > 0 \quad (45)$$

$$x_{rdl} = 0 \quad \forall r \in R_t; d \in D; l \in L; h \in H \setminus H_{td}; \tilde{\mu}_{lh} > 0 \quad (46)$$

5. A new parallel solution framework

We propose a parallel metaheuristic for the HSTP defined in Section 3 and modeled in Section 4. The approach builds on the diversification–intensification memory based (DIMB) framework proposed in Saviniec et al. (2018) for the same problem. The DIMB relies on a number of metaheuristic agents that work on parallel and share information via buffers of solutions. The method also

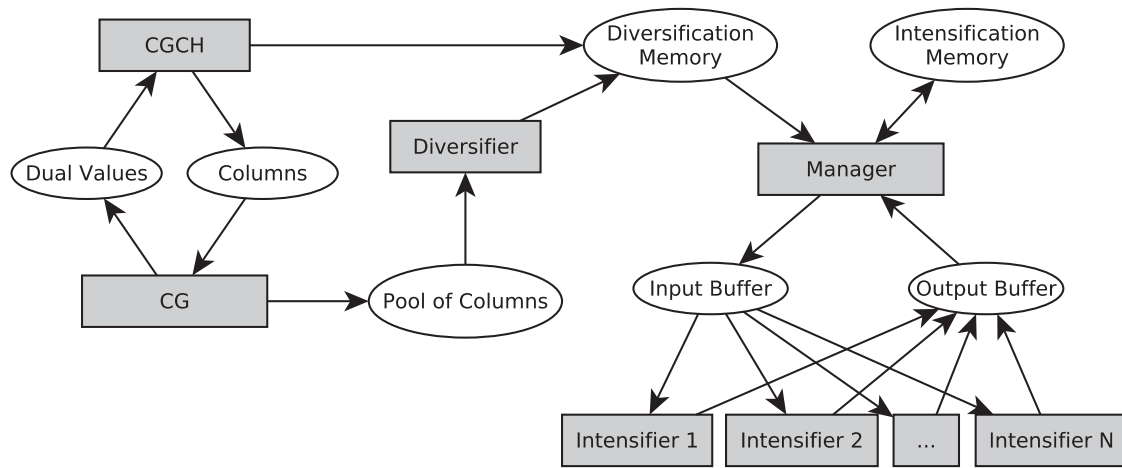

Fig. 2. Interactions among elements of the DIMB-CG framework.

Table 6
DIMB-CG main elements.

Element	Description
Manager	Coordinates the exchange of information between the intensifiers and the diversification and intensification memories.
Intensifiers	Improvement metaheuristic methods used to improve incumbent solutions.
Diversifier	Heuristic method used to find solutions with different structures.
Memories	Pools of feasible solutions.
CG and CGCH	Column generation procedure to generate lower bounds and associated repair heuristic.

uses intensification and diversification memories to improve the efficiency of the search.

The proposed *diversification-intensification memory based with column generation* (DIMB-CG) extends the DIMB by incorporating new agents based on the column generation proposed for model EF2, described in Section 4.2.1. The column generation based agents are responsible for obtaining lower bounds for the problem. They also exploit the generated columns to build new feasible schedules that are used to diversify the search. Table 6 lists the main elements of the framework while Fig. 2 shows their main interactions.

An overview of the whole algorithm is in the following. The manager procedure implements policies to guide the search and to update the diversification and intensification memories of solutions. It works by sending solutions (selected from one of the two memories) to intensifiers and receiving solutions from them, via the two intermediate buffers (the input and output buffers). The intensifiers explore the neighborhoods of the received solutions, during a pre-specified amount of time. The best solutions found during the search are sent back to the manager.

The agent CG is an implementation of the column generation approach on model EF2 described earlier. At each iteration of the column generation, a lower bound on the objective function value is obtained. Moreover, the dual values from the relaxed master problem are sent to a constructive heuristic, CGCH. The CGCH uses pricing subproblems created with this dual information to create new columns and complete solutions. The columns are sent back to the CG master problem while the complete solutions are sent to the diversification memory. The columns in the master are also sent to the diversifier agent through a pool of columns. This agent generates additional solutions to the diversification memory. In the following section, details on each of these agents are presented.

5.1. Implementation details

In this subsection, we detail the behavior of each of the agents listed earlier. We focus on the added elements with respect to Saviniec et al. (2018).

5.1.1. Manager and intensifiers

Both the manager and intensifiers are implemented as in Saviniec et al. (2018). The manager controls the exchange of solutions between the intensifiers and the (diversification and intensification) memories. All intensifiers and both memories are initialized with solutions generated by the diversifier and the CGCH. Two events can trigger actions from the manager:

- An intensifier finds a new solution: this solution is compared with a random solution from the intensification memory. If the objective value of this new solution is better, it replaces the old solution in the intensification memory.
- An intensifier becomes idle: the manager feeds the intensifier agent with a solution from the diversification memory (with probability ρ) or from the intensification memory (with probability $1 - \rho$).

The intensifiers are copies of the Iterated Local Search algorithm used in Saviniec et al. (2018). A brief explanation of the algorithm has been added for convenience in Appendix B.

5.1.2. Column generation

The column generation agent (CG) works as described in Section 4.2.1 with the sole additional feature that the master problem is updated not only with columns generated from its own pricing problems Q_t (implemented as the MIP described in (34)–(44)) but also with columns generated by the CGCH.

5.1.3. Column generation constructive heuristic

For the CGCH agent, we start with a fix-and-optimize constructive approach: the solution is built by solving the pricing problems Q_t sequentially. After a given pricing problem is solved and a schedule is obtained for a given teacher t , this part of the solution is fixed. Subsequent subproblems include additional constraints to avoid any clashes with the already-fixed variables. Due to the myopic nature of the procedure, it frequently happens that the pricing problems become infeasible after enough variables are fixed.

Whenever an infeasible subproblem is found, we run a repair procedure based on proximity search (Fischetti & Monaci, 2014). This is done by using a modified version of the model, where the objective function is to minimize the Hamming distance between

the new feasible solution and the current infeasible partial solution. We use the compact model CF1 described in [Appendix A](#), which relies on variables x_{rdh} indicating if a course r is fulfilled in period h of day d . Let J be the subset of variables x_{rdh} in model CF1 which are already fixed in the current partial solution, and $J_0 \subset J$ ($J_1 \subset J$) be the subset of these variables that have values set to zero (one). Our repair model can be written as:

$$\text{Minimize} \quad \sum_{x_{rdh} \in J_0} x_{rdh} + \sum_{x_{rdh} \in J_1} (1 - x_{rdh}) \quad (47)$$

Subject to:

$$\begin{aligned} & (A.2) - (A.21) \\ & x_{rdh} \in \{0, 1\} \quad \forall r \in R; d \in D; h \in H \end{aligned} \quad (48)$$

The objective function forces the problem to find the closest feasible solution in the neighborhood of the current partial solution (in terms of the Hamming distance). This strategy somehow preserves the structure of the solution built so far. Also, due to the strong relaxation grip of the model ([Fischetti & Monaci, 2014](#)), this correction problem tends to be easily solved.

5.1.4. Diversifier

The diversifier agent is responsible for feeding the diversification memory with solutions constructed by combining columns from the pool of columns. At each iteration, a random column is selected for each teacher and concatenated to form a possible infeasible solution (with clashes in classes' schedules). The new solution is repaired and improved by an iterated local search algorithm (see [Appendix B](#)) during a pre-specified amount of time and sent to the diversification memory.

6. Computational experiments

In this section, we conduct several experiments to evaluate our models and the proposed parallel algorithm. Experiments concerning the models are discussed in [Section 6.1](#), while those of the parallel algorithm are analyzed in [Section 6.2](#). In both cases, the experiments use the problem described in [Section 3](#) and two close variants. The three considered testbeds are:

- HSTP-A: in this variant, we test the proposed methods on problem described in [Section 3](#) using the 34 instances proposed by [Saviniec and Constantino \(2017\)](#), which are described in [Table 7](#). These instances come from 13 high schools located on State of Paraná, which is in southern Brazil. To this variant, we use the objective function penalty parameters ($\alpha_2 = \alpha_3 = \alpha_4 = 100,000$, $\alpha_5 = 100$, $\alpha_6 = 25$ and $\alpha_7 = \alpha_8 = \alpha_9 = \alpha_{10} = 10$) suggested by [Saviniec et al. \(2018\)](#), which prioritize courses' preferences over teachers' preferences. This penalties parameters were defined based on the priority given by the schools to each requirement. On all schools, the priority given to each requirement used to be the same, as all schools were following the same Paraná's education rules.
- HSTP-B: in this variant, we test the proposed methods on problem introduced by [Souza \(2000\)](#) using the author's instances, which are described in [Table 8](#). The problem and the instances come from the State of Minas Gerais, which is in northeastern Brazil. In this problem, requirements 1 to 5 are considered to be hard, requirements 7 to 9 are soft, and requirements 6 and 10 are ignored. As suggested in [Souza et al. \(2004\)](#), we use the following penalty parameters in the objective function: $\alpha_2 = \alpha_3 = \alpha_4 = 100,000$, $\alpha_5 = 10,000$, $\alpha_7 = 1$, $\alpha_8 = 3$ and $\alpha_9 = 9$. Although this problem comes from real world, the largest instances are artificial, which makes difficult to draw conclusions about algorithm's performance.

Table 7

Features of the instances proposed by [Saviniec and Constantino \(2017\)](#). The columns present the number of classes ($|C|$), teachers ($|T|$), days ($|D|$), periods per day ($|H|$), the total number of weekly lessons ($\sum_{r \in R} \tilde{\theta}_r$) and the total number of required double lessons ($\sum_{r \in R} \tilde{\pi}_r$) for each instance.

- HSTP-C: in this variant, the goal is to test the methods over a modified version of problem HSTP-B, which was proposed in the Third International Timetabling Competition 2011. This new problem is composed of all requirements of problem HSTP-B with the inclusion of requirement 6 as a hard requirement, which makes the problem harder to be solved by heuristics. To this purpose, we used the instances described in [Table 7](#), which provide real cases that are larger than those introduced by [Souza \(2000\)](#), shown in [Table 8](#). The objective function penalty parameters are the same suggested in [Saviniec et al. \(2018\)](#): $\alpha_2 = \alpha_3 = \alpha_4 = 100,000$, $\alpha_5 = 10,000$, $\alpha_6 = 5000$, $\alpha_7 = 1$, $\alpha_8 = 3$ and $\alpha_9 = 9$.

All implementations were coded in C++ and compiled with GNU Compiler Collection 4.4.7. Concert Technology Libraries from IBM CPLEX 12.6 are used to solve the mixed-integer programming

models. The experiments were performed on a computer Intel Xeon E5-2680v2 (2.8 gigahertz) with two cores and 128 gigabytes of RAM, running Red Hat Enterprise Linux 6.5.

6.1. Experiments with the proposed models

In this section, the goal is to analyze the efficacy of the proposed extended formulations and column generation procedure (for EF2). We report the following experiments:

- **Section 6.1.1:** In order to empirically study the efficacy of the proposed models in terms of the bounds they can provide, we compare the linear relaxation of EF1, EF1-cuts (EF1 augmented with Fenchel cuts), and EF2 with that of the compact formulation CF1, from Saviniec et al. (2018), on problem HSTP-A.
- **Section 6.1.2:** To understand the efficacy of the first formulation when used within a MIP black-box approach, we compare the performance of CPLEX when applied to EF1-cuts and CF1, in terms of the quality of primal and dual bounds and the number of instances with a proved optimal solution in a time limit of three hours.
- **Section 6.1.3:** To evaluate the performance of the models to a variant of the problem, the two proposed formulations are adjusted to model problem HSTP-B. We compare their results with results of formulations previously published for the same problem.
- **Section 6.1.4:** To evaluate the performance of the models to another variant of the problem, the two proposed formulations are adjusted and applied to solve the problem HSTP-C.

6.1.1. The linear program of EF1 and EF2 compared to CF1 on problem HSTP-A

Table 9 compares the quality of the proposed formulations, EF1 and EF2, with formulation CF1 on problem HSTP-A. Tests were run with CPLEX's default settings. For each formulation, we present the execution time (Time) and the linear program objective function (LP). We also present the same metrics, for formulation EF1 with the addition of the Fenchel cuts described in Section 4.1.1 (EF1-cuts), the best results are shown in bold font. The column (Improv.) also provides, for each proposed formulation, the percentage improvement between its LP objective value and that of formulation CF1, which is calculated as $improvement = 100 \cdot (LP - LP_{CF1}) \div LP$.

The figures in Table 9 show that EF1 runs faster and obtains linear bounds 21.09 % better than CF1, on average. The addition of Fenchel cuts can slightly improve linear relaxation bounds with the price of a considerable increase in computational time. In the case of formulation EF2, the improvements obtained are even better than the ones obtained by EF1 and EF1-cuts. However, it required about three times more computational time than EF1-cuts.

6.1.2. The integer program of EF1-cuts compared to CF1 on problem HSTP-A

In this section, we compare both primal and dual bounds obtained by CPLEX when using the proposed formulation EF1-cuts and the compact formulation CF1. Table 10 presents, for each formulation, the execution time (Time), the best lower bound (LB), the objective value of the best integer solution (UB), and the associated optimality gap ($Gap = 100 \cdot (UB - LB) \div UB$) on the tested

Table 10

The integer program of formulation EF1-cuts compared to CF1 on problem HSTP-A (TL = 3 hours).

Table 11

The lower bounds of formulation EF2 on problem HSTP-B.

ID	Optimal	Time (seconds)	NoC	LB	Gap
1	202	14.66	371	202	0.00
2	333	24.60	848	333	0.00
3	423	22.54	904	423	0.00
4	652	35.08	1364	652	0.00
5	762	39.73	1677	762	0.00
6	756	89.80	2025	756	0.00
7	1017	82.39	2216	1017	0.00

instances. In column Time, TL means that the time limit of three hours was reached without proof of optimality. The best LB and UB found for each instance are shown in bold font. Finally, the last row (Rank) presents the number of instances in which optimality was proved, or the best LB/UB were obtained.

The results in Table 10 indicate that formulation EF1-cuts can be used to obtain better bounds and prove more optimal solutions than the compact formulation CF1.

6.1.3. Results of EF1-cuts and EF2 compared to leading models on problem HSTP-B

In this section, we report the results obtained with formulations EF1 and EF2 when they are adapted to deal with problem HSTP-B. We use the instances shown in Table 8, which have optimal solutions known. Table 11 shows that the column generation procedure presented for EF2 is able to find optimal lower bounds for all

instances tested. The table presents the execution time (Time), the number of generated columns (NoC), and the lower bound (LB) obtained for each instance. These results are competitive with Santos et al. (2012) and Dorneles et al. (2017), which reported the same lower bounds with their column generation approaches. For these tests, CPLEX was run with a single thread, and its remaining parameters were set to default.

We also compare the performance of EF1-cuts with the compact formulation based on multi-commodity flow problems (CF-MCFP) by Dorneles et al. (2017). Table 12 shows, for both formulations, the best lower bounds obtained (LB), the best integer solutions (UB), and their optimality gaps (Gap) with a time limit of 2h (as used in Dorneles et al., 2017). For these instances, we also report the linear programming objective functions for EF1 (column LP) and EF1-cuts (LP_{cuts}), and the time needed to obtain them.

Formulations EF1 and CF-MCFP presented the same linear programming relaxation values shown in column LP. Formulation EF1-Cuts also improved these values via the Fenchel cuts. Regarding the integer programs, our formulation only performed worse than CF-MCFP in the number of best integer solutions. It ranked four best solutions against six of CF-MCFP. Our formulation also did not find a feasible solution to instance 7 within the time limit of two hours. On the other hand, EF1-Cuts provided the best lower bounds for all instances and proved the optimality of three instances while CF-MCFP proved the optimality only for two instances. We also observe that in instances 4 and 7, the Fenchel cuts led to optimal lower bounds.

Table 12

Formulation EF1-cuts compared to CF-MCFP on problem HSTP-B (TL = 2 hours).

ID	EF1		EF1-cuts					CF-MCFP		
	Time (seconds)	LP	Time (seconds)	LP _{cuts}	LB	UB	Gap	LB ^a	UB	Gap
1	0.08	189	1.66	190	202	202	0.00	190.24	202	5.82
2	0.67	333	18.84	333	333	333	0.00	333	333	0.00
3	0.39	414	19.29	414	418	444	5.86	413.99	429	3.50
4	2.08	643	83.92	652	652	652	0.00	652	652	0.00
5	4.05	756	273.95	757	757.50	763	0.72	756.02	777	2.70
6	6.06	738	375.48	750	750	935	19.79	739.52	804	8.02
7	12.69	999	842.92	1017	1017	–	–	1006.58	1645	38.81
Rank:					7	4	3	2	6	2

^a Dorneles et al. (2017) did not report the lower bounds (LB) of their integer programs after two hours. We calculated these values by the formula $LB = UB \cdot (1 - Gap \div 100)$, where Gap was reported to be the CPLEX's optimality gap.

Table 13

Results of formulations EF1-cuts and EF2 on problem HSTP-C.

6.1.4. Results of EF1-cuts and EF2 on problem HSTP-C

In this section, we report the results of formulations EF1-cuts and EF2 adapted to solve the problem HSTP-C. For this problem, we consider the instances of Table 7.

The results are shown in Table 13. For this variant, instances 15 and 22 are infeasible. For the remaining instances, the table compares the lower bounds of EF1-cuts and EF2. The columns labeled with (Gap) present, for each formulation, the gaps between its lower bounds (LB) and the best integer solutions (UB) of EF1-cuts. The best gaps are shown in bold font. For this problem, both

formulations ranked the same number of best lower bounds. However, formulation EF1-cuts performed slightly better than EF2 in terms of the quality of obtained lower bounds. As an overall result, we could prove the optimality for 25 out of the 32 instances that are not infeasible.

6.2. Experiments with the proposed parallel algorithm

In this section, we present two experiment sets to assess our parallel algorithm DIMB-CG.

Table 14

CG run-time speed-ups and percentage of additional columns generated when employing the heuristic CGCH.

	HSTP-A	HSTP-B	HSTP-C
Avg. speed-up:	1.54	2.29	1.23

Table 16

Quality of the CGCH solutions.

	HSTP-A	HSTP-B	HSTP-C
Avg. opt. gap:	19.17	2.74	10.57

- **Section 6.2.1:** The goal here is to test the efficacy of the new column generation-based agent, we test the effect of inserting the CGCH extra columns into the master program of the CG procedure. We also analyze the behavior of the two strategies used in our constructive heuristic CGCH and the quality of its solutions.

- **Section 6.2.2:** To analyze the overall performance of the method proposed, we compare our algorithm DIMB-CG with the best parallel algorithm proposed in Saviniec et al. (2018).

In all tests, the algorithm DIMB-CG was allowed to execute during a time limit of 625 seconds, as in Saviniec et al. (2018), and 25 independent trials were carried out for each instance.

6.2.1. Analysis of the heuristic CGCH

In Table 14, we analyze the CG run-time speed-ups, and the percentage of additional columns (PoAC) generated when the extra columns of the heuristic CGCH are also inserted into the master program of the column generation (strategy denoted as CG+CGCH). This table shows that the convergence of the CG procedure is accelerated when the extra columns are also added to its master program. We observe that large speed-ups of 1.54, 2.29 and 1.23 were obtained for problems HSTP-A, HSTP-B and HSTP-C, respectively, due to the use of the new agent. However, we cannot observe any apparent relation between the number of extra columns generated and the speed-ups obtained.

In Table 15, we analyze the effectiveness of the fix-and-optimize and proximity search strategies used by our CGCH heuristic in constructing feasible solutions. In the table, Avg. PoS1 is the fix-and-optimize average percentage of success in constructing feasible solutions (e.g., PoS1 = 1.7 means that the fix-and-optimize strategy generates feasible solutions in only 1.7 % of the cases). In the second row, Avg. PoPPS shows the average percentage of pricing problems that the fix-and-optimize strategy solves without failing. Namely, before it reaches an infeasible pricing problem (e.g., PoPPS = 85.0 means that, on average, the fix-and-

optimize strategy succeed in solving 85% of the pricing problems until reaching an infeasibility). Finally, Avg. PoS2 is the proximity search average percentage of success in repairing the infeasible partial solutions received from the fix-and-optimize strategy (e.g., PoS2 = 100.0 means that the proximity search strategy can repair all infeasible solutions received). This table shows that although the fix-and-optimize strategy fails with high rates, the proximity search repair strategy can repair almost all infeasible partial solutions generated by the fix-and-optimize strategy, making this hybrid approach very effective in practice.

In Table 16, we analyze the quality of the best solutions constructed by the heuristic CGCH. This table shows that the proposed heuristic is very effective indeed: it builds feasible solutions with an average optimality gap of 19.17% for problem HSTP-A and 10.57%

for problem HSTP-C. For problem HSTP-B, the produced solutions are almost optimal, with an average gap of only 2.74%. We also observed that the less constrained the problem, more the proximity search was effective in not only repairing, but also improving the partial fix-and-optimize solutions.

6.2.2. Analysis of the algorithm DIMB-CG

In this section, we compare the proposed algorithm DIMB-CG with the best version of the parallel algorithm of Saviniec et al. (2018), called DIMB-19I1D-8-0.05.

In Table 17, we present the results for problem HSTP-A. Column "Best LB" shows the best lower bounds reported in Section 6.1. For each algorithm, we provide its median (Median) and best (Best) solutions, and the associated gaps (Gap) compared to the best-known

lower bounds. The best results are shown in bold font. This table shows that the proposed algorithm performs better than DIMB-1911D-8-0.05, both in terms of median and best solutions. In column “ToBS”, we also show the DIMB-CG median execution time required to stagnate in the last improved solution (i.e. the best solution). This column shows that the most difficult instances for the method are instances 23 and 24. In instance 23, for example, the algorithm takes approximately 491 seconds to find near-optimal solutions ($\approx 8.6\%$ of optimality gap). For some small instances, such as 10, 15 and 18 to 20, the algorithm only takes a few seconds to find the optimal solutions.

In Table 18, we present the results for problem HSTP-B. This table shows that both algorithms were able to find the optimal solutions for all instances in the median case. Column (ToBS) shows that the algorithm DIMB-CG is almost instantaneous to find optimal solutions for these instances, except for instance 3, in which it takes around 31 seconds to reach the optimal solutions.

Table 19 presents the results for problem HSTP-C. This table shows that the algorithm DIMB-CG performs better than the algorithm DIMB-1911D-8-0.05 in median solutions, but it is less effective in the number of best solutions. As the problem HSTP-C is more constrained than the problem HSTP-A, the algorithm DIMB-CG takes longer to make the last improvement, see column “ToBS”. However, for most of the tested instances, it is still able to reach near-optimal solutions expending running time much smaller than the specified time limit.

7. Conclusions

In this paper, we conducted a study with mixed-integer programming formulations and parallel metaheuristic based algorithms for high school timetabling problems. We proposed two extended pattern-based formulations and a cooperative parallel algorithm.

The first proposed formulation, EF1, introduced original variables associated with *layouts*, indicating the presence/absence of a teacher or course in a teaching slot. This formulation allowed for the use of a black-box solver to tackle instances of practical size, as long as the number of teaching slots in a day is kept small. This strategy was shown to have performance similar to the best available compact formulations. Also effective was the introduction of Fenchel cuts which increased the obtained lower bounds with reasonable computational costs. The second formulation EF2 was solved within a column generation framework and also presented competitive results in comparison to other extended formulations available in the literature (Dorneles et al., 2017; Santos et al., 2012), often obtaining lower bounds with the same value as the known optimal solutions.

The proposed parallel algorithm DIMB-CG found near-optimal solutions for all studied problems outperforming previous methods in three variants of the HSTP. The main contribution of this algorithm is the introduction of new agents that exploit the developed column generation method for EF2 to generate new feasible solutions. It was done using a novel combination of fix-and-optimize and proximity search heuristics. The combination of these two heuristics proved successful and can certainly be extended to other problems. Future work also includes the investigation of branch-and-price algorithms making use of the proposed column generation approach. Particularly interesting is the study of the behavior of the introduced reduced-information columns (layouts) in this context.

Appendix A. Compact formulation

This section describes a reformulation of the MIP model proposed in Saviniec et al. (2018), denoted here by CF1. In this reformulation, a timetable output can be represented by a set of binary variables x_{rdh} , for all $(r, d, h) \in R \times D \times H$. Let us consider the notation defined in Table A.20, the HSTP can be formulated as follows:

$$\begin{aligned} \text{Minimize} \quad & \alpha_5 \sum_{r \in R} \sum_{d \in D} \hat{\delta}_{rd} + \alpha_6 \sum_{r \in R} \sum_{d \in D} \sum_{h=1}^{|H|-2} \hat{j}_{rdh} + \alpha_7 \sum_{r \in R} \hat{\pi}_r \\ & + \alpha_8 \sum_{t \in T} \sum_{d \in D} \sum_{k=1}^{|H_{td}|-2} \hat{i}_{tdk} + \alpha_9 \sum_{t \in T} \sum_{d \in D} \hat{d}_{td} + \alpha_{10} \cdot \hat{\beta} \end{aligned} \quad (\text{A.1})$$

Subject to:

$$\sum_{d \in D} \sum_{h \in H} x_{rdh} = \tilde{\theta}_r \quad \forall r \in R \quad (\text{A.2})$$

$$\sum_{r \in R_c} x_{rdh} = 1 \quad \forall c \in C; d \in D; h \in H \quad (\text{A.3})$$

$$\sum_{r \in R_t} x_{rdh} \leq 1 \quad \forall t \in T; d \in D; h \in H_{td} \quad (\text{A.4})$$

$$\sum_{r \in R_t} x_{rdh} = 0 \quad \forall t \in T; d \in D; h \in H \setminus H_{td} \quad (\text{A.5})$$

Table A.20
Notation used in formulation CF1.

Notation	Definition
Decision variables	
$x_{rdh} \in \{0, 1\}$	Indicates whether a course $r \in R$ is assigned to a period $h \in H$ of a day $d \in D$.
Auxiliary variables	
$\hat{\delta}_{rd} \in \mathbb{N}$	The number of lessons that exceeds the limit $\tilde{\delta}_r$ in a day d for a course r .
$\hat{j}_{rdh} \in \{0, 1\}$	Indicates whether the schedule of a course r has a gap at period h of day d .
$\phi_{rdh} \in \{0, 1\}$	Indicates whether a course r has a double lesson at periods $h-1$ and h of day d .
$\hat{\pi}_r \in \mathbb{N}$	The number of unmet weekly double lessons for a course r .
$\hat{d}_{td} \in \{0, 1\}$	Indicates whether a teacher t works in a day d .
$\hat{i}_{tdk} \in \{0, 1\}$	Indicates whether a teacher t is idle at period k of day d .
$\hat{\beta} \in \mathbb{N}$	The greatest value among all teachers' extra working days.

$$\hat{\delta}_{rd} \geq \sum_{h \in H} x_{rdh} - \tilde{\delta}_r \quad \forall r \in R; d \in D \quad (A.6)$$

$$\begin{aligned} \hat{j}_{rdh} &\geq x_{rdi} - x_{rdh} + x_{rdj} - 1 \quad \forall r \in R; d \in D; h = 1, \dots, |H| - 2; \\ i &= 0, \dots, h - 1; j = h + 1, \dots, |H| - 1 \end{aligned} \quad (A.7)$$

$$\hat{\phi}_{rdh} \leq x_{rdh} \quad \forall r \in R; d \in D; h = 1, \dots, |H| - 1 \quad (A.8)$$

$$\hat{\phi}_{rdh} \leq x_{r,d,h-1} \quad \forall r \in R; d \in D; h = 1, \dots, |H| - 1 \quad (A.9)$$

$$\hat{\phi}_{rdh} \leq 1 - \hat{\phi}_{r,d,h-1} \quad \forall r \in R; d \in D; h = 2, \dots, |H| - 1 \quad (A.10)$$

$$\hat{\pi}_r \geq \tilde{\pi}_r - \sum_{d \in D} \sum_{h=1}^{|H|-1} \hat{\phi}_{rdh} \quad \forall r \in R \quad (A.11)$$

$$\begin{aligned} \hat{i}_{tdk} &\geq \sum_{r \in R_t} (x_{r,d,h_i} - x_{r,d,h_k} + x_{r,d,h_j}) - 1 \\ \forall t &\in T; d \in D; k = 1, \dots, |H_{td}| - 2; \\ i &= 0, \dots, k - 1; j = k + 1, \dots, |H_{td}| - 1; \\ h_i, h_k, h_j &\in H_{td} \end{aligned} \quad (A.12)$$

$$\hat{d}_{td} \geq \sum_{r \in R_t} x_{rdh} \quad \forall t \in T; d \in D; h \in H_{td} \quad (A.13)$$

$$\hat{\beta} \geq \sum_{d \in D} \hat{d}_{td} - \tilde{d}_t \quad \forall t \in T \quad (A.14)$$

$$\hat{\delta}_{rd} \geq 0 \quad \forall r \in R; d \in D \quad (A.15)$$

$$\hat{j}_{rdh} \geq 0 \quad \forall r \in R; d \in D; h = 1, \dots, |H| - 2 \quad (A.16)$$

$$\hat{\phi}_{rdh} \geq 0 \quad \forall r \in R; d \in D; h = 1, \dots, |H| - 1 \quad (A.17)$$

$$\hat{\pi}_r \geq 0 \quad \forall r \in R \quad (A.18)$$

$$\hat{i}_{tdk} \geq 0 \quad \forall t \in T; d \in D; k = 1, \dots, |H_{td}| - 2 \quad (A.19)$$

$$\hat{d}_{td} \geq 0 \quad \forall t \in T; d \in D \quad (A.20)$$

$$\hat{\beta} \geq 0 \quad (A.21)$$

$$x_{rdh} \in \{0, 1\} \quad \forall r \in R; d \in D; h \in H \quad (A.22)$$

The objective function (A.1) minimizes the cost of breaking soft requirements 5 to 10. Eqs. (A.2) to (A.5) model the hard requirements. Constraints (A.2) ensure that the weekly lessons of all courses are scheduled. Constraints (A.3) to (A.4) avoid clashes in classes and teachers' schedules, and constraints (A.5) prevent the assignment of teachers to unavailable periods.

The other equations are related to the soft requirements. Soft requirement 5 is modeled by Eq. (A.6), in which the auxiliary variables $\hat{\delta}_{rd}$ measure the excess of lessons in daily workloads that are greater than $\tilde{\delta}_r$, for each course r . The number of gaps in courses' schedules are computed with the introduction of the auxiliary variables \hat{j}_{rdh} and the constraints (A.7). The variable \hat{j}_{rdh} indicates whether a course r has a gap at period h of day d . The soft requirement regarding the meeting of double lessons is modeled by the set of constraints (A.8) to (A.11). For each course r , the auxiliary variables $\hat{\phi}_{rdh}$ identify whether a double lesson ends in a period $h \in \{1, \dots, |H| - 1\}$ of a day $d \in D$, and the number of unmet weekly double lessons is quantified in constraint (A.11), with the help of the additional auxiliary variable $\hat{\pi}_r$.

To compute idle periods in teachers' schedules, we introduce the constraints (A.12), and the auxiliary variables \hat{i}_{tdk} , that flag if a teacher t is idle in a period $h_k \in H_{td}$ ($k = 1, \dots, |H_{td}| - 2$) of a day $d \in D$. The computation of idle periods in teachers' schedules is similar to the computation of gaps in courses' schedules, except that the variables \hat{i} are omitted for periods in which the teachers are unavailable (Saviniec et al., 2018). As an example, consider $H = \{0, 1, 2, 3, 4\}$, and suppose that a teacher t is unavailable at periods 2 and 3 during a day d . Therefore, $H_{td} = \{0, 1, 4\}$ and only the variable $\hat{i}_{t,d,1}$ is considered, which means that unavailable periods are disregarded. In constraints (A.13), we model the minimization of busy days on teachers' schedules. For each teacher t , the auxiliary variables \hat{d}_{td} flag if he/she is working on day d . Finally, the last set of constraints (A.14) model the balancing on teachers' extra working days.

Appendix B. The stand-alone iterated local search

This section describes the sequential Iterated Local Search (ILS) adapted from Saviniec et al. (2018), that we employ in our parallel algorithm of Section 5. We use two versions of this metaheuristic. One works within the diversifier agent while the other works within the intensifier agents. Each version also manipulates a different type of timetable encoding, that we call type I and type II. The timetable type I is manipulated by the ILS that works within the diversifier and the timetable type II is manipulated by the ILS that works within the intensifiers. Following, we discuss the two timetable encodings (Section B.1), the neighborhood structure and objective function evaluation (Section B.2), then lastly, the ILS pseudo-code is presented (Section B.3).

B.1. Timetable encodings

Let S be an array of all timeslots $(d, h) \in D \times H$. We illustrate the timetables type I and II in Fig. B.3. Both of them are based on the persistent data structure proposed in Saviniec et al. (2018). In both cases, the core of the encodings is an array of timeslots. In a timetabling encoding, either type I or II, each timeslot points to a second-layer array of pointers, each one of those pointing to a tuple $(r \in R, c \in C, t \in T, \theta_r, \delta_r, \tilde{\pi}_r)$ that represents a course $r \in R$ and its parameters, the associated class, teacher, number of weekly lessons, limit of lessons per day, and number of required double lessons, respectively. In timetable encoding type I (resp. type II), the i th position in the second-layer array indicates a course associated to the i th teacher (resp. class). In the remainder of this paper, to improve the presentation, instead of showing a pointer to a course tuple itself, we show only the teacher or class ID belonging to the tuple being pointed by the pointer.

B.2. Neighborhood structure and objective function

Neighboring solutions are generated via the torque neighborhood operator (TQ) (Saviniec & Constantino, 2017). This operator

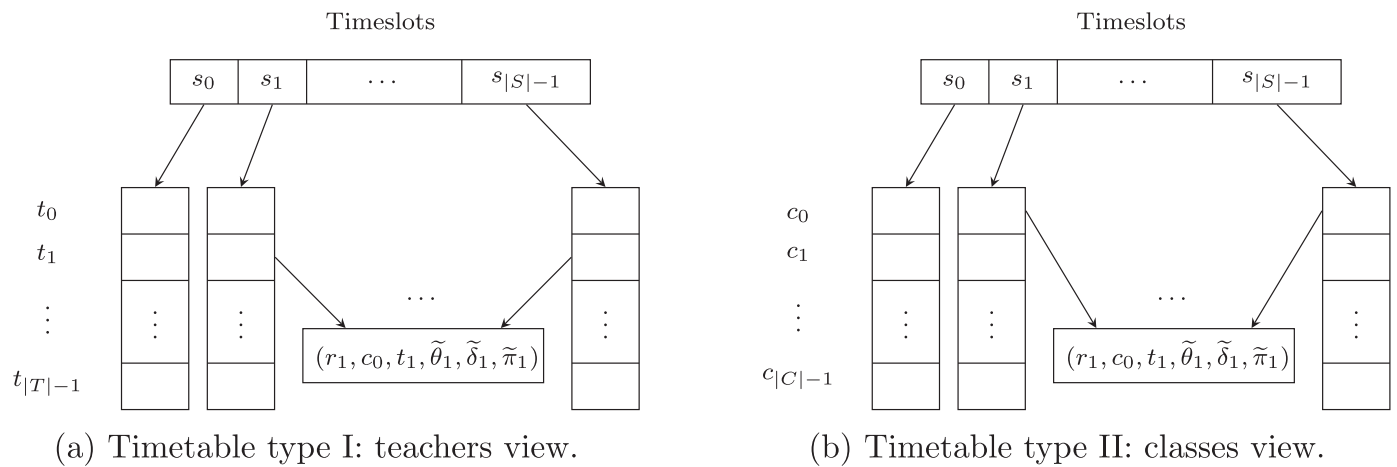

Fig. B.3. Timetable encodings.

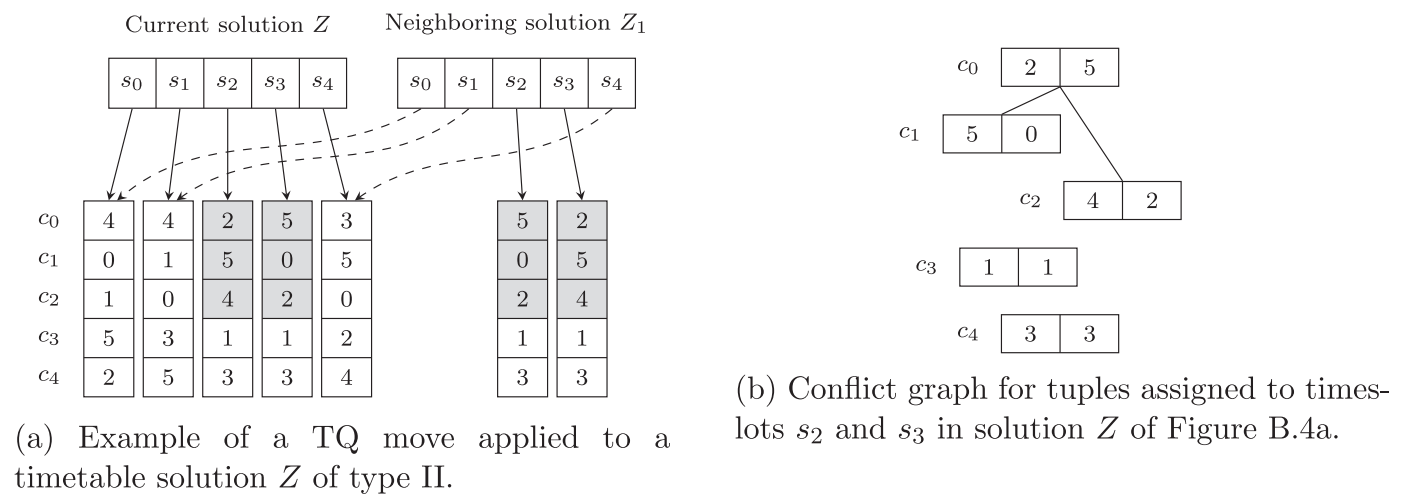

Fig. B.4. Neighborhood structure with timetable type II.

identifies chains of two-swap moves that must be performed together so that new clashes in classes' (or teachers') schedules are avoided. A *two-swap* move consists in exchanging the course tuples of a teacher $t \in T$ (or class $c \in C$), that are assigned to two different timeslots. Chains of two-swap moves are identified by conflict graphs. Fig. B.4 shows an example of a TQ move with the timetable type II. In this example, we identify all possible moves for tuples that are assigned to timeslots s_2 and s_3 of the timetable solution Z , shown in Fig. B.4(a). The conflict graph is shown in Fig. B.4(b), in which there is one vertex for each class, representing its tuples (remember, we are showing only the associated teachers), and edges connecting conflicting vertexes. The neighboring solution Z_1 (Fig. B.4(a)) is generated by applying a two-swap move for each class in the connected component $\{c_0, c_1, c_2\}$. Neighboring solutions with timetable type I are obtained similarly as made with timetable type II.

Both ILS versions work in an infeasible space of solutions in which some of the hard requirements are relaxed and penalized in the objective function. For the ILS version which works inside the intensifier agents, the timetable encoding type II ensures that hard requirements 1 and 2 are never violated by TQ moves. Therefore, we relax hard requirements 3 and 4, and penalize them using the following objective function:

$$\text{Minimize } f(Z) = (1) + \sum_{i \in \{3,4\}} \alpha_i \cdot V_i \quad (\text{B.1})$$

Which is the objective function of the model EF1 plus the number of violations V_i , for hard requirements 3 and 4, times a penalty parameter α_i .

For the ILS version which works inside the diversifier agent, the timetabling encoding type I ensures that hard requirements 1 and 3 are never broken by the employed operator. Hence, we relax hard requirements 2 and 4, and penalize them according to the following objective function:

$$\text{Minimize } f(X) = (1) + \sum_{i \in \{2,4\}} \alpha_i \cdot V_i \quad (\text{B.2})$$

B.3. The ILS algorithm

Let SP be the array of all timeslot pairs (s_i, s_j) , for $i, j = 0, \dots, |S| - 1$ and $i \neq j$, we show the pseudo-code of the sequential ILS in Algorithm 1. At each iteration of the main loop (lines 3 to 23), the algorithm performs a random perturbation in its global best solution (line 4), followed by a local search in the resulting solution (lines 5 to 18), to reach a local optimum. If the local optimum is better than or equal to the global best solution (line 19), it is accepted. Otherwise, it is rejected. The algorithm is controlled by either, a maximum number of iterations or a time limit. The local search phase (lines 5 to 18) is a first improvement strategy that starts in a random index of SP (line 7), and inspects the next $|SP|$ consecutive timeslot pairs (lines 8 to 17) to find new improving solutions.

Algorithm 1 Pseudo-code of the sequential ILS adapted from Saviniec et al. (2018).

ILS(Z_0 , $timeOut$, $iterOut$)

```

1   $Z^* = Z_0$ 
2   $k = 0$ 
3  while ( $elapsedTime < timeOut$  and  $k < iterOut$ ) {
4       $Z = PERTURBATION(Z^*)$  // a random TQ move
5      do {
6           $best = f(Z)$ 
7           $i = \text{take a random integer in the range}$ 
8               $0 \leq i \leq |SP| - 1$ 
9          for ( $j = 1$  to  $|SP|$ ) {
10              Compute the connected components for tuples
11                  assigned to timeslots  $sp_i$  of  $Z$ 
12              for (each connected component) {
13                  Generate a new neighboring solution
14                       $Z'$  from  $Z$ 
15                  if ( $f(Z') \leq f(Z)$ ) {
16                       $Z = Z'$ 
17                  }
18              }
19               $i = (i + 1) \bmod |SP|$ 
20          }
21          while ( $f(Z) < best$ )
22          if ( $f(Z) \leq f(Z^*)$ ) {
23               $Z^* = Z$ 
24          }
25           $k = k + 1$ 
26      }
27  return  $Z^*$ 

```
